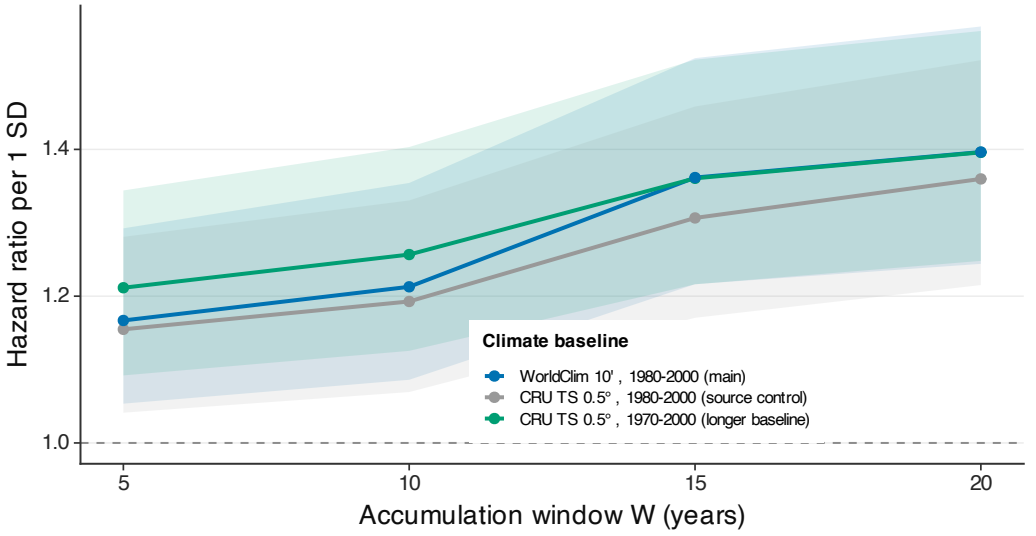
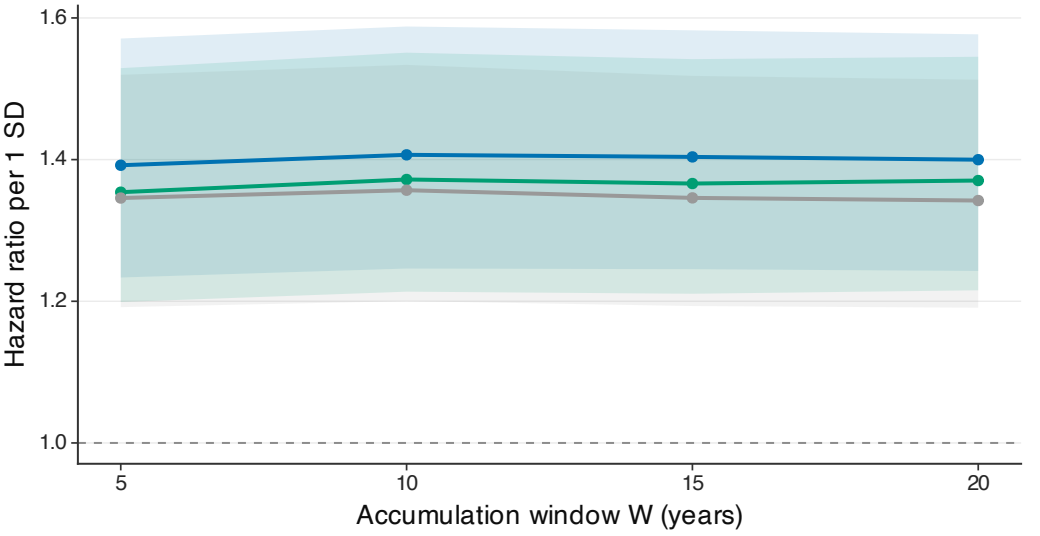
a **The warming signal is decadal, not annual**

Every source and baseline gives the same rise from W = 5 to W = 20



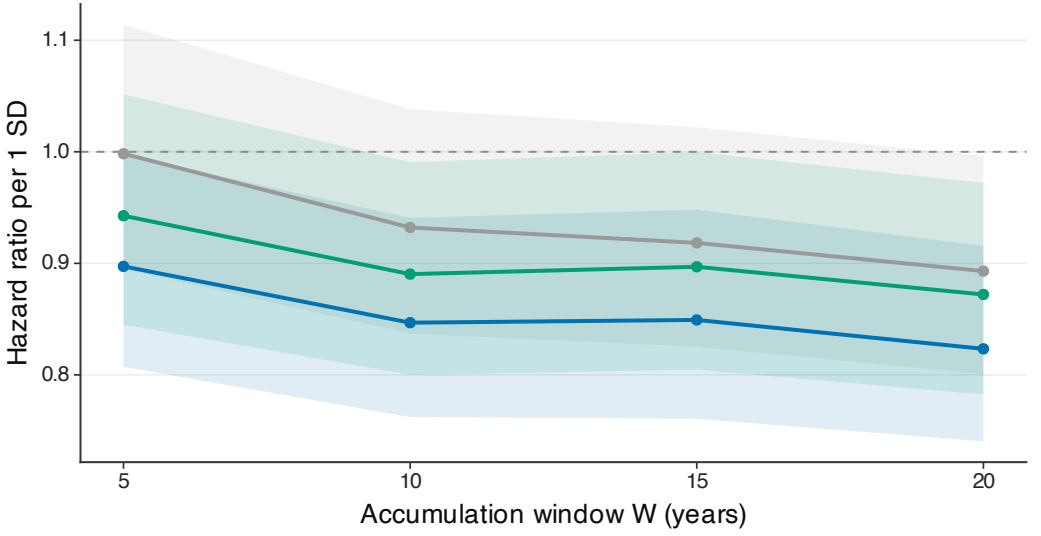
b **The effort coefficient does not care**

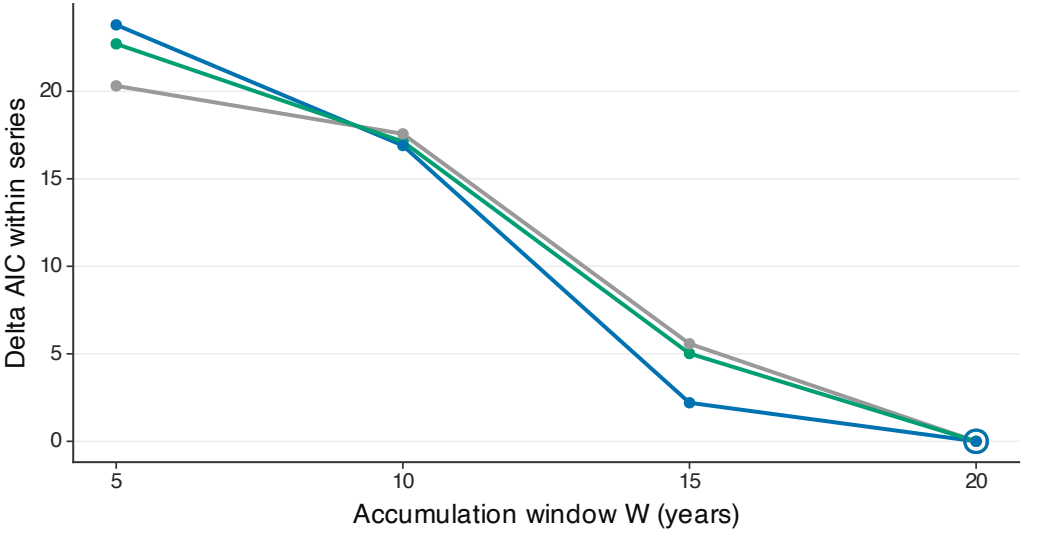
1.34-1.41 across all twelve combinations,
as expected if the two terms are separately identified



c **The interaction is negative throughout**

Warming x effort stays below 1 at every window, source and baseline



d **All three series select a 15-20 year window**


Circles mark the AIC optimum; W = 15 is within 2.2-5.6 units of it in every series.
A finer grid (3-23 yr, Extended Data Table 2) places the optimum at 18-20 yr
and shows AIC rising again by 23 yr,
so the optimum is interior rather than an artefact of stopping at 20.
