Mechanistic projection of new-record generation hazard

Discrete-time cloglog model; CMIP6 4-GCM delta applied to both province and species-range climate; only rows inside the fitted covariate support

Latent generation hazard relative to the 2024 baseline (log2 colour scale); province-by-year shocks set to expectation and reporting completeness set to 1. Base map GS(2019)1822. Pale grey: inside the analysis scope but no cell falls within the fitted covariate range for that scenario and horizon. Mid grey: outside the analysis scope (Taiwan, Hong Kong, Macao and the jointly administered area, none of which have provincial effort coverage). Only species-province rows whose warming and effort fall inside the 1st-99th percentile of the fitted data are aggregated. The percentage in each panel is the share of rows that qualify: by 2050 under SSP5-8.5 only 2% do, so the later horizons rest on very few comparable cases and should be read as illustrations.
