a
The warming signal is decadal, not annual
Every source and baseline gives the same rise from W = 5 to W = 20
Hazard ratio per 1 SD
Accumulation window W (years)
Climate baseline
WorldClim 10' , 1980-2000 (main)
CRU TS 0.5° , 1980-2000 (source control)
CRU TS 0.5° , 1970-2000 (longer baseline)
b
The effort coefficient does not care
1.37-1.43 across all twelve combinations,
as expected if the two terms are separately identified
Hazard ratio per 1 SD
Accumulation window W (years)
c
The interaction is negative throughout
Warming x effort stays below 1 at every window, source and baseline
Hazard ratio per 1 SD
Accumulation window W (years)
d
All three series select a 15-20 year window
Circles mark the AIC optimum; W = 15 is within 2.1-6.0 units of it in every series.
A finer grid (3-23 yr, Extended Data Table 2) places the optimum at 18-20 yr
and shows AIC rising again by 23 yr,
so the optimum is interior rather than an artefact of stopping at 20.
Delta AIC within series
Accumulation window W (years)
