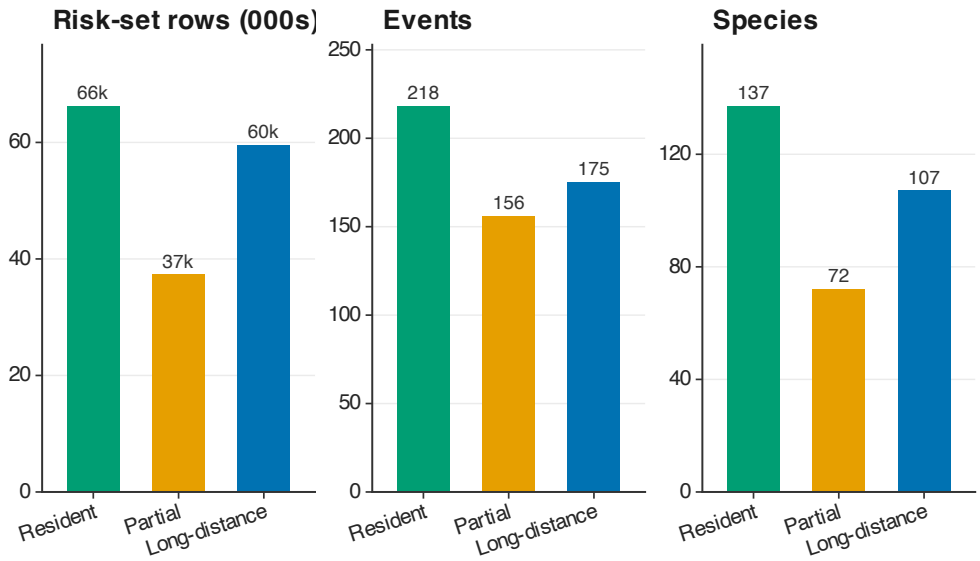
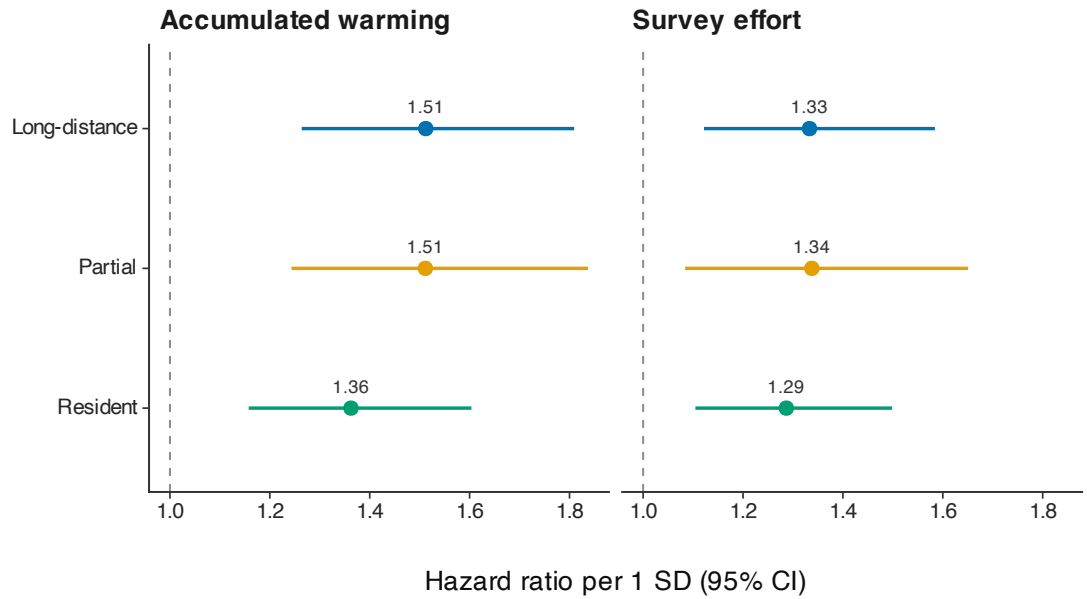
a **Power comes from all three groups**

Every group carries at least 156 events, so none is a token category



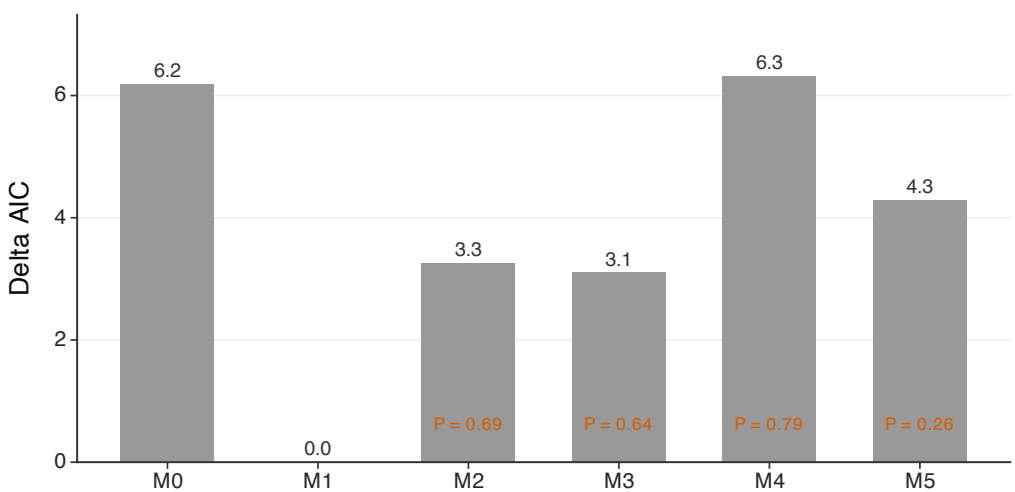
b **Both drivers act in every migratory group**

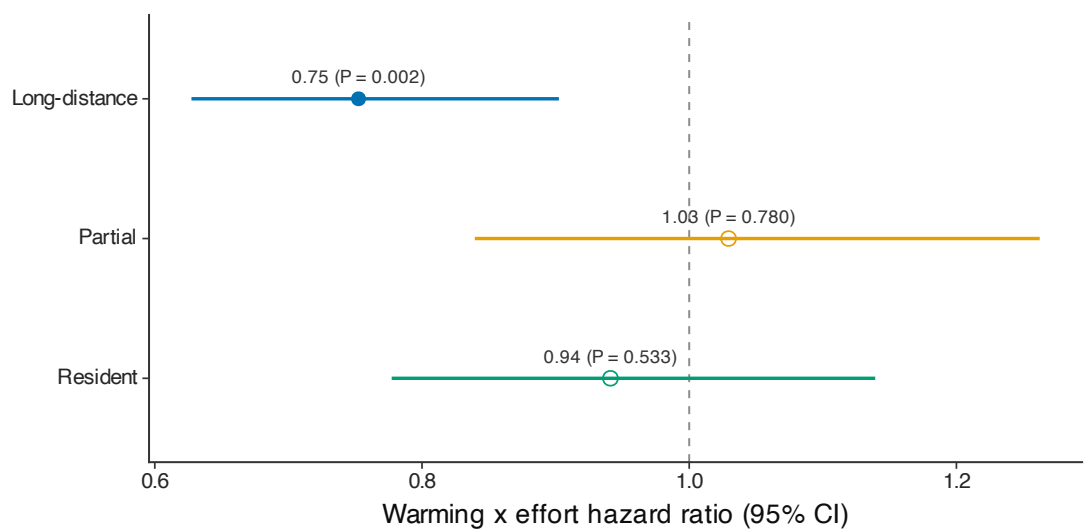
Confidence intervals overlap heavily; no group is exempt from either driver



c **Migratory strategy shifts the baseline, not the slopes**

M0 main model | M1 + migratory main effect | M2 + warming x migratory | M3 + effort x migratory | M4 + both | M5 + three-way warming x effort x migratory. Red: likelihood-ratio P against M1



d **A hint, not a result**


The interaction is significant only among long-distance migrants, but the formal test for heterogeneity is not (three-way LR P = 0.26; long-distance vs resident contrast P = 0.078). With 156-218 events per group the design cannot resolve group differences in an interaction.
